

Banba Kato yama

He states that atoms may not exist in their free state but may exist in the combined state in the form of molecules.

Any combination of atoms, whether free or combined, is called a molecule. Further, but the formation of chemical reactions by combining two or more different atoms together to form a molecule.

Law of Chemical Combination

Elements — substances whose molecules are made up of only one type of atoms.

Compounds — substances whose molecules are made up of more than one type of atoms and called compounds.

Properties of compound are different from the properties of elements they are made up of.

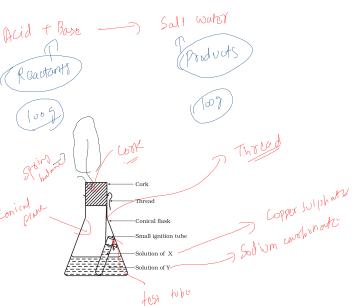

The combination takes place via chemical reaction following certain laws called laws of Chemical Combination

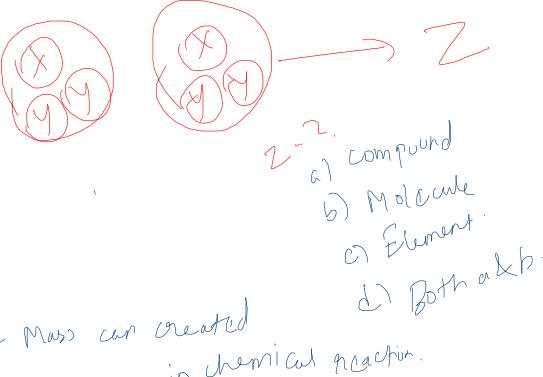

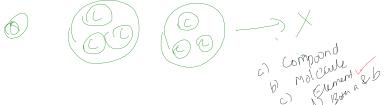

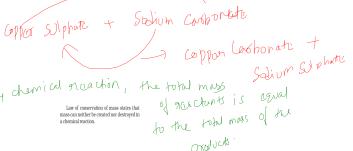

When two or more substances combine to form an entirely different product

Principle Law of Chemical Combination

LAW OF CONSERVATION OF MASS

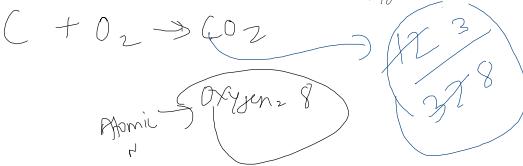

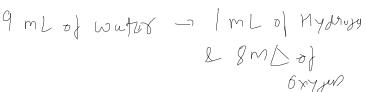

i) $X \text{ gm}$
ii) $X \text{ gm}$

Law of Constant Proportions

Mass of H/Mass of O = $2/16 = 1:8$

"In a chemical substance the elements are always present in definite proportions by mass".

Q) When 12g of NaHCO_3 is added to a solution of HCl weighing 12g , it is observed that 2.2g of CO_2 is released into atmosphere. The residue left behind is found to weigh 12g .

is in agreement of which law?

mass of reactants = mass of products

$$\text{mass of products} = 2.2\text{g} + 12\text{g} = 14.2\text{g}$$

✓ There is no loss or gain of mass during the reaction.

✓ Hence, the given observation prove the law of conservation of mass.

a) Calculate the mass of carbon present in 1g of CO_2

3g of Carbon combine with 8g of oxygen to form 11g of CO_2

$$11\text{g of CO}_2 \text{ contains C} = 3\text{g}$$

$$11\text{g of CO}_2 \text{ contains O} = \frac{3}{11} \times 8 = \frac{24}{11} = 2.18\text{g}$$

Q) CaCO_3 contains 40% calcium, 12% carbon and 48% oxygen by mass. Knowing that the law of constant composition holds good, calculate the mass of the constituent elements present in 2g of CaCO_3 .

$$1\text{g Ca} + 12\text{g C} + 48\text{g O}$$

$$= 100\text{g CaCO}_3$$

$$10\text{g Ca} + 3\text{g of C} + 12\text{g of O}$$

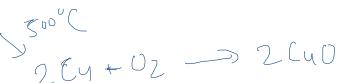

$$= 25\text{g of CaCO}_3$$

of if your model

$$1190$$

b) What mass of AgNO_3 will react with 5.85g of NaCl to produce 14.3g of AgCl & 8.5g of NaNO_3 , if the law of conservation of mass holds true.

$$\begin{array}{ll} \text{Mass of reactants} & \text{Mass of products} \\ n + 5.85 & = 8.5 + 14.35 \end{array}$$

$$1.75\text{g of Cu} \rightarrow 2.19\text{g of CuO}$$

$$\begin{aligned} \text{o/o of Cu in the oxide} &= \frac{1.75}{2.19} \times 100 \\ &= 79.9 \text{ o/o} \end{aligned}$$

$$\begin{aligned} \text{o/o of Cu in the oxide} &= \frac{1.14}{1.13} \times 100 \\ &= 100 - 79.9 = 20.1 \text{ o/o} \end{aligned}$$

law of constant proportion

$$\begin{aligned} 2\text{g of Cu} &\rightarrow 17\text{g of O} \\ 25\text{g Cu} &\rightarrow \frac{10}{28} \times 2 = 5.85\text{g of O} \\ 28\text{g Cu} &\rightarrow 6.85\text{g of O} \end{aligned}$$

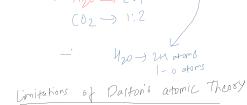

$$\begin{aligned} 2\text{g of CuO} &\rightarrow 3\text{g of O} \\ 25\text{g CuO} &\rightarrow \frac{3}{10} \times 2 = 6.2\text{g of O} \\ 28\text{g CuO} &\rightarrow 6.2\text{g of O} \end{aligned}$$

$$\begin{aligned} 2\text{g of CuO} &\rightarrow 17\text{g of O} \\ 25\text{g CuO} &\rightarrow \frac{12}{28} \times 2 = 6.9\text{g of O} \\ 28\text{g CuO} &\rightarrow 6.9\text{g of O} \end{aligned}$$

c) CuO was prepared by 2 diff methods, In one case, 1.75g of the metal gave 2.19g of oxide. In the 2nd case, 1.14g of the metal gave 1.13g of oxide. Show that given data illustrates law of constant proportion:

Dalton's Atomic Theory

- 1 Atoms are building blocks of every matter particles called atoms, which participate in chemical reactions.
- 2 Atoms are indestructible particles which cannot be created or destroyed.
- 3 Atoms of a given element are identical.
- 4 Atoms of different elements have different properties.
- 5 Masses of different elements are proportional to the number of atoms present in equal weights.
- 6 Masses of different elements are proportional to the number of atoms present in equal weights.
- 7 The relative number and kinds of atoms are constant in all substances.

Limitations of Dalton's atomic Theory

i) Atom is no longer considered as the smallest indivisible mass.

pt, e⁻ & neutrons in nucleus. Atom = pt + e⁻. Atoms have no mass.

(ii) Atoms of the same element may have different masses.

(iii) Atoms of the different elements may have same masses.

iv) Substances made up of the same kind of atoms may have different properties.

Diamond → Hardest, Best conductor of electricity
Graphite → Weak, Good conductor of electricity.

What is an Atom?

→ An atom is defined as the smallest particle of an element which may or may not be capable of free existence.

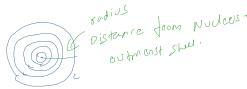

→ However, it is the smallest particle that takes part in a chemical reaction.

STM - Scanning Tunneling Microscope.

↳ See diagram.

→ All atoms are considered to be spherical.

→ Sizes are expressed in terms of their radii, called atomic radii.

→ Atoms are so small in size that their radii are usually expressed in nanometres (nm).

$1\text{ nm} = 10^9\text{ nm}$ $1\text{ nm} = 10^{-9}\text{ m}$
radii of the atoms are in the orders of 10^{-10} m

Hydrogen	Carbon	Oxygen
Phosphorus	Sulfur	Iodine
Copper	Lanthan	Silver
Gold	Platinum	Palladium
Silicon	Argon	Platinum
Manganese	Hydrogen	Hydrogen
Sodium	Natrium	Natrium
Potassium	Kalium	Kalium

Fig. 2.30 Symbols for some elements as proposed by Dalton

Modern Symbol of Element

→ When more & more elements were discovered, International Committee was set up, called International Union of Pure and Applied Chemistry (IUPAC), which approved the names of diff. elements.

→ Names of most of the elements have been taken from English, some elements however have been named from Latin, German or Greek.

Latin	English
Copper	Copper
Iron	Iron
Gold	Gold
Silicon	Silicon
Manganese	Manganese
Sodium	Sodium
Potassium	Kalium

Atomic mass

for ex - actual mass of an atom of hydrogen is $1.673 \times 10^{-24}\text{ g}$

→ It was found convenient to compare the masses of atoms of different elements with some reference atom.

→ The masses thus obtained are called relative atomic masses.

→ Reference chosen in the beginning was hydrogen atom because it was the lightest element.

→ Using hydrogen as the reference, the masses of other elements came out to be found.

→ Reference was changed to oxygen taken as 16 because oxygen combined with most of the elements.

- considered relevant due to two reasons:
- oxygen reacted with a large number of elements
- this atomic mass unit gave masses of most of the elements as whole numbers.

However, in 1961 for a numerically acceptable atomic mass, carbon 12 became the reference atom for measuring atomic masses. One atomic mass unit is a mass unit equal to exactly one-twelfth ($\frac{1}{12}$) the mass of one atom of carbon 12. The relative atomic masses of all elements have been found with respect to an atom of carbon 12.

Atomic mass

→ The atomic mass of an element is the relative mass of its atoms as compared with the mass of an atom of carbon twelve isotope taken as 12.

masses of atoms are measured in atomic mass units. One atomic mass unit is a mass unit equal to exactly one-twelfth ($\frac{1}{12}$) the mass of one atom of carbon 12.

The relative atomic masses of all elements have been found with respect to an atom of carbon 12.

$$1\text{ amu} = \frac{1}{12}\text{ th of mass C-12 isotope}$$

→ Atomic mass of an element may, therefore, also be defined as the number of times an atom of that element is heavier than $\frac{1}{12}$ th of the mass of an atom of C-12 isotope.

What is a Molecule?

↳ A molecule is a group of two or more atoms which are held together strongly by some kind of attractive forces.

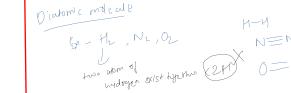

↳ Such an attractive force holding the atoms together is called a chemical bond.

↳ Depending upon whether the molecule contains one, two, three, four etc. atoms, are called monatomic, diatomic, triatomic etc.

Monatomic molecule

↳ Noble gases - Helium neon etc exist in single atoms.
→ Hence their molecules are monoatomic.

(Ex) He Single atom of hydrogen exists hydrogen H_2

Diatomic molecule

H_2 - H_2 , N_2 , O_2
↓
two atom of hydrogen exist hydrogen H_2

Tetraatomic molecule
Ex. P_4

Molecules containing more than four atoms are called polyatomic.

→ The number of atoms present in one molecule of the substance is called atomicity.

Molecules of a compound
Molecules of a compound means one or more atoms of different elements combined together in a definite proportion by mass to form a group that can exist alone.

(Ex: Molecules of water, molecules of salt)

Distinctive features
Ex: Salt, water, etc.

Tetrahedral molecules
Ex: Hydrogen Fluoride (HF_2), ammonia (NH_3)

Molecular mass

→ Molecular mass of a substance (Element or Compound) is the relative mass of its molecules as compared with that of an atom of C-12 (Atomic mass no. 12).

→ In other words, molecular mass of a substance represents the number of times the molecule of that substance is heavier than $\frac{1}{12}$ th mass of an atom of C-12 isotope.

Calculation of Molecular Mass

$$\text{O}_3 \rightarrow 3 \times 16 = 48 \text{ u.}$$

$$\text{H}_2\text{O} \rightarrow 2 \times \text{atomic mass of hydrogen} + 1 \times \text{atomic mass of oxygen}$$

$$\rightarrow 2 \times 1 + 16 = 18 \text{ u}$$

$$\text{CO}_2 \rightarrow 1 \times \text{atomic mass of carbon} + 2 \times \text{atomic mass of oxygen}$$

$$\rightarrow 12 + 2 \times 16 = 44 \text{ u}$$

$$(b) \text{C}_12\text{H}_{22}\text{O}_11 \rightarrow 12 \times 12 + 1 \times 22 + 16 \times 11$$

$$= 144 + 22 + 174$$

$$= 342 \text{ u}$$

$$(b) \text{Al}_2(\text{SO}_4)_3 \rightarrow 27 \times 2 + 3 \times [16 \times 4]$$

$$= 54 + 120$$

$$= 174$$

$$(c) \text{CuSO}_4 \cdot 5\text{H}_2\text{O} \rightarrow 63.5 + 32 + (16 \times 4)$$

$$= 249.5 + 5(2 \times 1 + 1)$$

Ions & Ionic compounds

→ An atom or a group of atoms which carries positive or negative charge is called an ion.

→ The ion carrying positive charge is called a cation & the ion carrying -ve charge is called anion.

→ Ion consisting of only single atoms are called monatomic ions whereas an ion consisting of a group of atoms is called a polyatomic ion.

→ Compounds consisting of cations & anions are called ionic compounds.

→ In any ionic compound, the total positive charge carried by the cation is equal to the total negative charge carried by the anion so that as whole, the ionic compound is electrically neutral.

Naming

→ Cation is always named first followed by anion.

→ $\text{Al}_2(\text{SO}_4)_3 \rightarrow$ Aluminium sulphate

Writing chemical formula

Na^+ → 1 unit of +ve charge

Ca^{2+} → 2 units of +ve charge

Al^{3+} →

U^- → 1 unit -ve charge

O^{2-} → 2 units -ve charge

(Valency = 1)

Monovalent cations

$\text{H}^+, \text{Na}^+, \text{K}^+$

(Valency = 2)

Divalent cations

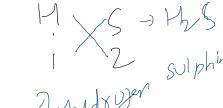

$\text{Ca}^{2+}, \text{Mg}^{2+}$

(Valency = 3)

Trivalent cation

$\text{Al}^{3+}, \text{Fe}^{3+}$

Formula of simple molecular compounds

Partides \rightarrow Atoms, molecules, ion & C^- , pt^+ , N .

$$1 \text{ dozen} = 12$$

$$1 \text{ score} = 20$$

$$1 \text{ mole of H} = 6.022 \times 10^{23} \text{ atoms of hydrogen.}$$

$$1 \text{ mole of H}_2\text{O} = 6.022 \times 10^{23} \text{ molecules of H}_2\text{O}$$

$$\text{Mass of 1 H atom} = 1 \text{ u.}$$

$$6.022 \times 10^{23} \text{ atoms of H} = 1 \text{ g} \rightarrow \text{Gram atomic mass}$$

$$1 \text{ mole of Hydrogen} = 1 \text{ g} = 6.022 \times 10^{23} \text{ atoms} \rightarrow \text{Molar mass}$$

$$\text{Mass of 1 Oxygen atom} = 16 \text{ u.}$$

$$\text{Mass of 1 mole of O atom} = 16 \text{ g.}$$

\downarrow

6.022×10^{23} atoms

$$1 \text{ mole of O} = \frac{\text{Gram Atomic mass}}{\text{Molar mass}}$$

Gram atomic mass

Atomic mass of an element is expressed in amu or u because it is the relative mass of the atom of that element.

Atomic mass expressed in grams is called gram atomic mass of that element.

$$\text{Ex} \quad \text{Atomic mass of oxygen} = 16 \text{ u} \\ \text{Gram atomic mass} = 16 \text{ g}$$

The amount of an element having mass equal to gram atomic mass is called "gram atom" of that element.

Gram molecular mass

$$\text{Molecular mass} \quad \text{Ex} \quad \text{H}_2\text{O} \rightarrow 1 \times 2 + 16 = 18 \text{ u}$$

Molecular mass expressed in grams is called gram molecular mass of that substance.

The amount of the substance having mass equal to its gram molecular mass is called "gram molecule" of the substance.
